

Introduction to Machine Learning

Supervised Regression

Polynomial Regression Models

Learning goals

- Learn about general form of linear model
- See how to add flexibility by using polynomials
- Understand that more flexibility is not necessarily better

INCREASING FLEXIBILITY

- Recall our definition of LM: model y as linear combo of features
- But: isn't that pretty **inflexible**?
- E.g., here, y does not seem to be a linear function of x ...

... but relation to x^3 looks pretty linear!

- Many other trafo's conceivable, e.g., $\sin(x_1)$, $\max(0, x_2)$, $\sqrt{x_3}, \dots$
- Turns out we can use LM much more **flexibly** (and: it's still linear)
 \rightsquigarrow interpretation might get less straightforward, though

THE LINEAR MODEL

- Recall what we previously defined as LM:

$$f(x) = \theta_0 + \sum_{j=1}^p \theta_j x_j = \theta_0 + \theta_1 x_1 + \cdots + \theta_p x_p \quad (1)$$

- Actually, just special case of "true" LM
- The linear model with basis functions ϕ_j :**

$$f(\mathbf{x}) = \theta_0 + \sum_{j=1}^p \theta_j \phi_j(x_j) = \theta_0 + \theta_1 \phi_1(x_1) + \cdots + \theta_p \phi_p(x_p)$$

- In Eq. 1, we implicitly use identity trafo: $\phi_j = \text{id}_x : x \mapsto x \quad \forall j$
 \rightsquigarrow we often say LM and imply $\phi_j = \text{id}_x$

THE LINEAR MODEL

- Are models like $f(\mathbf{x}) = \theta_0 + \theta_1 x^2$ **really linear**?

- Certainly not in covariates:

$$\begin{aligned} a \cdot f(x, \theta) + b \cdot f(x_*, \theta) &= \theta_0(a + b) + \theta_1(ax^2 + bx_*^2) \\ &\neq \theta_0 + \theta_1(ax + bx_*)^2 \\ &= f(ax + bx_*, \theta) \end{aligned}$$

- Crucially, however, **linear in params**:

$$\begin{aligned} a \cdot f(x, \theta) + b \cdot f(x, \theta^*) &= a\theta_0 + b\theta_0^* + (a\theta_1 + b\theta_1^*)x^2 \\ &= f(x, a\theta + b\theta^*) \end{aligned}$$

- NB: we still call design matrix **X**, incorporating possible trafos:

$$\mathbf{X} = \begin{pmatrix} 1 & \phi_1(x_1^{(1)}) & \dots & \phi_p(x_p^{(1)}) \\ \vdots & \vdots & & \vdots \\ 1 & \phi_1(x_1^{(n)}) & \dots & \phi_p(x_p^{(n)}) \end{pmatrix}$$

\rightsquigarrow solution via normal equations as usual

$$\theta = (0.5, 0.4)^T$$

$$\theta = (1.0, 0.8)^T$$

$$\theta = (1.5, 1.2)^T$$

POLYNOMIAL REGRESSION

- Simple & flexible choice for basis funs: **d -polynomials**
- Idea: map x_j to (weighted) sum of its monomials up to order $d \in \mathbb{N}$

$$\phi^{(d)} : \mathbb{R} \rightarrow \mathbb{R}, \quad x_j \mapsto \sum_{k=1}^d \beta_k x_j^k$$

- How to estimate coefficients β_k ?
 - Both LM & polynomials **linear** in their params \rightsquigarrow merge
 - E.g., $f(\mathbf{x}) = \theta_0 + \theta_1 \phi^{(d)}(x) = \theta_0 + \sum_{k=1}^d \theta_{1,k} x^k$

$$\rightsquigarrow \mathbf{X} = \begin{pmatrix} 1 & x^{(1)} & (x^{(1)})^2 & \dots & (x^{(1)})^d \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x^{(n)} & (x^{(n)})^2 & \dots & (x^{(n)})^d \end{pmatrix}, \quad \boldsymbol{\theta} \in \mathbb{R}^{d+1}$$

POLYNOMIAL REGRESSION – EXAMPLES

Univariate regression, $d \in \{1, 5\}$

- Data-generating process:

$$y = 0.5 \sin(x) + \epsilon,$$

$$\epsilon \sim \mathcal{N}(0, 0.3^2)$$

- Model:

$$f(x) = \theta_0 + \sum_{k=1}^d \theta_{1,k} x^k$$

Bivariate regression, $d = 7$

- Data-generating process:

$$y = 1 + 2x_1 + x_2^3 + \epsilon,$$

$$\epsilon \sim \mathcal{N}(0, 0.5^2)$$

- Model:

$$f(x) = \theta_0 + \theta_1 x_1 + \sum_{k=1}^7 \theta_{2,k} x_2^k$$

COMPLEXITY OF POLYNOMIALS

- Higher d allows to learn more complex functions
~> richer hyp space / higher **capacity**

- Should we then simply let $d \rightarrow \infty$?
 - **No**: data contains random **noise** – not part of true DGP
 - Model with overly high capacity learns all those spurious patterns ~> poor generalization to new data
 - Also, higher d can lead to oscillation esp. at bounds (Runge's phenomenon¹)

¹ Interpolation of m equidistant points with d -polynomial only well-conditioned for $d < 2\sqrt{m}$.
Plot: 50 points, models with $d \geq 14$ instable (under equidistance assumption).

BIKE RENTAL EXAMPLE

- OpenML task `dailybike`: predict rentals from weather conditions
- Hunch: non-linear effect of temperature \rightsquigarrow include with polynomial:

$$f(\mathbf{x}) = \sum_{k=1}^d \theta_{\text{temperature},k} x_{\text{temperature}}^k + \theta_{\text{season}} x_{\text{season}} + \theta_{\text{humidity}} x_{\text{humidity}}$$

- Test error² confirms suspicion \rightsquigarrow minimal for $d = 3$

- Conclusion: flexible effects can improve fit/performance

²Reliable insights about model performance only via separate test dataset not used during training (here computed via 10-fold *cross validation*). Much more on this in Evaluation chapter.
